

CI/CD Pipeline with Jenkins + Nexus (Local Docker Setup)

This document summarizes the setup done for creating a CI/CD pipeline using Jenkins and Nexus Repository Manager running on Docker locally. It also includes common issues faced and their resolutions.

Steps Performed:

1. Installed Jenkins using Docker and configured pipelines.
2. Configured Maven project to produce WAR file.
3. Installed Nexus Repository using Docker.
4. Fixed initial Nexus authentication using admin password from /nexus-data/admin.password.
5. Created Maven Release repository in Nexus (Version Policy: Release).
6. Updated settings.xml in Jenkins container to configure credentials for deployment.
7. Configured distributionManagement block inside pom.xml.
8. Faced issue: 400 Bad Request due to hostname (exciting_haslett) not resolving.
9. Fixed by using container name in URL instead of random host name.
10. Successfully deployed WAR file: verified in Nexus UI.

Interview Talking Points:

- CI/CD pipeline fully automated using Jenkins declarative pipeline.
- Used Nexus as artifact repository for WAR artifacts.
- Maven deploy plugin with credentials stored in ~/.m2/settings.xml.
- Docker networking troubleshooting, container DNS resolution issue fixed.
- Release repository configuration concept + deployment rules.
